(54) Title: AIRCRAFT PASSENGER SEAT AND IN-FLIGHT ENTERTAINMENT INTEGRATED ELECTRONICS

An aircraft seat assembly (60) (57) Abstract: including at least one electronic component (20, 22, 24, 26) usable by a passenger and an single integrated electronic systems which provides signal decoding, signal routing, data management, built in test, and power conversion for each user accessible electronic component which is installed in the seat assembly (60). The electronic components (20, 22, 24, 26) generally include at least a video display unit (20), an audio system (24), or a telephone (22). The integrated electronics system provides power conversion, signal routing, data management and other electronic requirements for each of the electronic components. The integrated electronics system of the present invention not only integrates power conversion and signal management responsabilities into one system, but also is integrated into the seat assembly (60).

AIRCRAFT PASSENGER SEAT AND IN-FLIGHT ENTERTAINMENT INTEGRATED ELECTRONICS

5

FIELD OF THE INVENTION

[0001] The present invention relates to integrated electronics, and more particularly to integrated electronics including multiple electronic systems for airline seat assemblies.

10

15

20

25

BACKGROUND OF THE INVENTION

[0002] Generally, aircraft are sold to airline companies as an engine and fuselage which the particular airline companies may customize. The aircraft manufacturer generally manufacturers aircraft for a wholesale or general market allowing the airlines to make additions and changes to the aircraft. Generally, airline companies install additional and supplementary elements, such as seats, In-Flight Entertainment system components, and galleys, into the aircraft after the aircraft has been completed, but before delivery. These additional elements assist or are useful to the passengers and may include newer or additional technology components. Some of these components include personal computer power outlets, phones, and the components capable of providing multiple video channel, audio channels, and data management.

themselves so that they can be accessed by passengers sitting in each seat. Currently, many seats in commercial aircraft include passenger control units, which control functions such as attendant call, a seat video display, a phone, or computer interface. Wiring bundles connect all of the seats and electronic components. The wiring bundles comprise all of the necessary electrical cabling. The wiring bundles run overhead in the aircraft down the sidewall, in a space between the sidewall and the exterior of the aircraft, and to the seats or through floor mounted junction boxes to the seats. Additional wiring also runs from seat to seat

30

connecting the various components. Each of the components has its own seat mounted wiring, circuitry, and electronics components, such as a seat electronics box (SEB) or a seat electronics unit (SEU). Much of the wiring, however, between the main wiring and the separate components is redundant, increasing the volume and the mass of wiring which simply replicates the functions of other wiring. In many instances a separate SEB/SEU performs similar or redundant functions for each component.

5

10

15

20

25

30

[0004] These multiple boxes and redundant wiring systems increase the weight, power consumption, and the volume of space required in an aircraft for their installation. In particular, the multiple redundant boxes reduce leg room and comfort of a passenger. Most significantly, the redundant circuitry increases the weight of the aircraft thereby decreasing pay load capacity and increasing the fuel consumption of an aircraft during powered flight. Furthermore, the components increase the total cost and weight of the final seat assembly. If a component fails, repair of the component may require replacing the affected component. This is particularly cumbersome when many of the components are manufactured by various vendors requiring vast stockpiles and disparate specialized knowledge in the maintenance and/or replacement of such components.

SUMMARY OF THE INVENTION

[0005] The above drawbacks are addressed by an integrated seat assembly in accordance with the present invention. An integrated seat assembly eliminates the multiple and redundant circuits reducing manufacturing time, costs, and weight.

[0006] A first preferred embodiment of the present invention comprises an integrated seat assembly having an integrated electronic assembly, adapted to be placed in an aircraft. The seat assembly has at least one seat portion. A component to be used by a passenger sitting in the seat assembly is provided. Finally, an electronic system which is

integrated into the one portion of the seat assembly provides power conversion, data management, and other functions for the component.

[0007] A second preferred embodiment of the present invention includes an airline seat assembly with multiple seat portions, having a plurality of electronic components to be used by a passenger. A single integrated electronics system distributes power, signal, and data management capabilities for the plurality of electronic components to be used by the passenger.

[0008] A third preferred embodiment of the present invention includes a seat portion that includes at least a seat back and armrest adapted to be used by a passenger in an aircraft. A plurality of passenger usable electronic components, including a video display unit, a telephone, an audio output, and a personal computer port, incorporated within the seat portion. In addition, a single power converter to transmit power to each of the plurality of electronic components, and, a ribbon cable operably associated with the power supply including a plurality of conductors that transmit power through at least one of said plurality of conductors to the electronic components. The ribbon cable may be installed between airplane and seat, seat to seat and within the seat.

20

5

10

15

[0009] A fourth preferred embodiment of the present invention includes a data processor function connecting a plurality of electronic components bi-directionally connected by fiber optic cable or a wireless interface to its data source.

25

[0010] Further areas of applicability of the present invention will become apparent from the detailed description provided hereinafter. It should be understood that the detailed description and specific examples, while indicating the preferred embodiments of the invention, are intended for purposes of illustration only and are not intended to limit the scope of the invention.

[0011] The present invention will become more fully understood from the detailed description and the accompanying drawings, wherein:

[0012] Figure 1 is a side elevation view of a pair of prior art airline seat assemblies; and

[0013] Figure 2 is a side elevation view of an integrated airline seat assembly according to the present invention.

5

25

30

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

With reference to Figure 1, an exemplary prior art seat [0014] assembly is shown. The first seat assembly 10 includes a seat back 12, a seat cushion 14, an arm portion 16, and a plurality of leg supports 18. The first seat assembly 10 typically includes several electronic components. The electronic components generally comprise at least a single or multifunction video display unit (VDU) 20, a telephone 22, an audio interface 24 and a personal control unit (PCU) 26. Figure 1 shows an exemplary configuration wherein the first seat assembly 10 is in a first row followed by a second seat assembly 10' in a second row. The portions of the second seat assembly 10' that are similar to the first seat assembly 10 are indicated with the same reference numeral augmented by a prime. The PCUs 26, 26' allow a passenger to control each of the electronic components included for that passenger's use. Generally, the VDU 20 on the first seat assembly 10 is controlled by the PCU 26' associated with the second seat assembly 10'. The telephone 22 on the first seat assembly 10 is available for use by the passenger seated in the second seat The PCU 26', also controls the volume of the audio assembly 10'. interface 24', and the signal being received by the VDU 20.

[0015] Each electronic component has a corresponding seat electronics box (SEB) or a seat electronics unit (SEU), housed in a plurality of boxes 30, that are mounted to the first seat assembly 10. The second seat assembly 10' also includes a plurality of boxes 30'. Each SEB/SEU box 30, 30' is mounted to its associated leg supports 18, 18'. The SEB/SEU boxes 30', 30' are generally large and bulky in size and

WO 03/050000 PCT/US02/36678 5

5

10

15

20

25

30

have exterior dimensions that are equal to a large amount of the space under the seat assemblies 10, 10'. Although the plurality of SEB/SEU boxes 30, 30' may not extend longitudinally under the entire seat assemblies 10,10', they can disrupt the ability of the passenger sitting behind the respective seat assemblies 10, 10' to position the passenger's legs comfortably or to stow carry-on baggage. Cable bundles 32 with multiple conductors extend from each SEB/SEU 30, 30' and run along aisleway 34 and interconnect the plurality of SEB/SEU boxes 30, 30' within a seat. The cable bundles 32 carry signals and power from a signal and power source 33 to and between seat assemblies 10, 10'. These cable bundles 32 also add to the weight and bulk of the seat assemblies 10, 10' and decrease the passenger-usable space inside the cabin of the aircraft and may decrease the performance reliability of the electronic components. Additional conductors 35 carry the signal or power from each SEB/SEU 30,30' to each of the electronic components.

Generally, the SEB/SEU boxes 30, 30' are line [0016] replaceable units (LRU). A LRU is a portion of a component which may be easily removed and replaced to ensure proper functioning of the component. Each seat component such as the VDU 20, and telephone 22, has its own SEB/SEU box 30. The SEB/SEU boxes 30, 30' are LRUs so that if at any time a component no longer works and the problem can be isolated to the SEB/SEU box 30, 30', then the SEB/SEU box can be replaced. Since each component requires its own SEB/SEU box 30, 30', there is a redundancy of such SEB/SEU 30, 30' box circuitry and the associated wiring. Generally, each SEB/SEU box 30, 30' will perform at least one of the following: power conversion, information management, Each SEB/SEU 30, 30' box is signal routing and data management. unique to the component to which it is connected. For example, if a SEB/SEU box 30, 30' is connected to a VDU 20, 20', then the SEB/SEU box 30, 30' transfers power to the VDU 20, 20', provides a signal decoder for the VDU 20, 20' and also interconnects the PCU 26, 26' with the

5

10

15

20

25

30

respective VDU 20, 20'. The redundancy of the SEB/SEU boxes 30, 30' also produces additional heat and draws redundant power.

With reference to Figure 2, an integrated seat assembly 60 in accordance with a preferred embodiment of the present invention is shown. The integrated seat assembly 60 includes several seat portions including a seat back 62, a seat cushion 64, and an arm portion 66; all seat portions are supported by multiple leg supports 67. The integrated seat assembly 60 also includes at least one seat or electronic component including a VDU 68, a phone 70, an audio output 72, a computer connection 74, and/or a PCU 76. The integrated seat assembly 60, according to the present invention, will not include other electronic boxes. Rather than providing individual components including SEB/SEUs 30, 30', all of the components are integrated into a universal or integrated electronics system. Therefore, all of the currently redundant SEB/SEUs 30, 30' are removed and replaced with a single or unitary integrated electronics distribution system where an integrated power converter 77 or router 78 is operably connected to all electronic components. Generally, the integrated power converter 77 or router 78 include bi-directional data flow to support a built in test function to monitor proper functioning of the electronic component. It will also be understood that the power converter and the router 78 may be LRUs to decrease maintenance time and resources.

[0018] Different variations of the integrated electronics system are discussed herein. It will be understood that transceiver and power converting operations may alternatively be integrated into the aircraft or any seat portion such as the seatback 62, the arm portion 66, or the seat cushion 64. Furthermore, the personal control unit 76 can include transceiver responsibilities for the seat or the electronic components including the VDU 68, the phone 70, the audio output 72, and the personal computer port 74. It will be understood that an aircraft will include a plurality of integrated seat assemblies 60 and all of the electronic components are interconnected, as are all integrated seat assemblies 60

5

10

15

20

25

30

in the aircraft, with an interconnection system. The interconnection system is selected from a wireless, fiber optic, or wire cabling system. One embodiment of the interconnection system includes a single ribbon cable 80 which carries power and a signal from a power and signal source 81 to each of the different electronic components. Different conductors 82 of ribbon cable 80 split off from the ribbon cable 80 coming from floor or aisleway 90 along the leg supports 67 to power each individual electronic component. Alternatively, the ribbon cable 80 provides power to the power converter 77 and a signal to the router 78 where upon the power and signal are then transmitted to the various electronic components. Therefore, the single ribbon cable 80 provides power to each of the electronic components installed in integrated seat assembly 60. This reduces the overall size and weight of the integrated seat assembly 60.

[0019] The only cable extending into the integrated seat assembly 60 is the ribbon cable 80 which provides power to the separate components. It will be understood that ribbon cable 80 may also carry a signal to each seat component or may provide only power to wireless components. The ribbon cable 80 has a very low profile (i.e., is very flat and thin) and may be easily concealed under carpeting in the aisleway 90 and concealed in the cushioning of the integrated seat assembly 60 itself. Furthermore, the ribbon cable 80 may reduce electrical noise and interference without requiring bulky electrical insulation materials to be employed.

[0020] An exemplary estimate of the weight reduction of wiring due to removal of the redundant wiring and SEB/SEUs is between about 20% and 40% on a 2000 design of a Boeing 767-400 commercial aircraft. The precise weight savings using the present invention will depend upon how many electronic components were installed in the previous seat design used by an airline company. Removal of redundant LRUs will provide a weight reduction of between about 30% and 50%. Not powering each of the additional SEB/SEU 30, 30', redundant components, and by

not using additional cables, power consumption is decreased by between about 20% and 40%.

[0021] The integrated seat assembly 60 is more easily serviced and upgraded. By removing the redundant systems, fewer electronic systems are available to break, thereby reducing the likelihood of frequent servicing. Additionally, the initial installation integration of the present invention into new designs is greatly reduced by not requiring multiple redundant components. Therefore, initial production and installation costs are reduced. This design concept further reduces the number of connectors in the electronic components, thereby increasing the reliability of the system.

5

10

15

[0022] The description of the invention is merely exemplary in nature and, thus, variations that do not depart from the gist of the invention are intended to be within the scope of the invention. Such variations are not to be regarded as a departure from the spirit and scope of the invention.

CLAIMS

What is claimed is:

- A single integrated electronics system for an airline seat
 assembly comprising:
 - a seat assembly including at least one seat portion;
 - a plurality of user accessible electronic components;
 - a single electronics distribution system placed into said seat portion;
- an interconnection system that operably interconnects said plurality of user interface components and said single electronics system; and wherein said single electronics system provides all power conversion requirements for each of said plurality of components.

- 2. The single integrated electronics system of claim 1, further comprising a personal control unit, wherein said personal control unit is a part of said single electronics distribution system.
- The single integrated electronics system of claim 2, wherein said at least one seat portion includes a seat-back and said single electronics distribution system is formed into said seat-back.
- The single integrated electronics system of claim 3, wherein said
 single electronics distribution system comprises a power converter or a router for each of said electronic components.
 - 5. The single integrated electronics system of claim 1, wherein said interconnection system comprises a ribbon cable adapted to substantially reduce electrical interference inside and outside said interconnection system.

15

20

- 6. The single integrated electronics system of claim 5, further comprising a plurality of said seat assemblies, wherein said ribbon cable comprises the physical interconnection between said plurality of seat assemblies and supplies power to said component.
- 7. The single integrated electronics system of claim 1, wherein said interconnection system carries power and a signal to said component.
- 25 8. The single integrated electronics system of claim 7, wherein said component includes a plurality of said components in each seat assembly, wherein said single electronics distribution system transfers said power and said signal from said ribbon cable to each of said plurality of components.
- 30 9. The single integrated electronics system of claim 8, wherein said plurality of components comprises a personal control unit, a video display, an

audio outlet, and a telephone; and wherein said personal control unit allows a user to control the plurality of components.

- 10. The single integrated electronics system of claim 1, wherein said plurality of components includes a video display unit, an audio interface, a computer interface, and a telephone.
- 11. The single integrated electronics system of claim 1, wherein at least one of said user accessible components is located in an arm portion ofsaid seat assembly.
 - 12. The single integrated electronics system of claim 1, wherein at least one of said user accessible components is located in a seat back of said seat assembly.

13. An aircraft seat assembly architecture comprising;
a seat assembly including at least one arm portion or one back
portion;

a seat component extending from said seat assembly including: a video display unit;

a telephone;

5

a unitary electronics distribution system including a ribbon cable integrated into said seat assembly; and

wherein said unitary electronics distribution system provides the 10 only power and information management system for each of said video display unit, said telephone, and said computer coupling.

14. The airline seat architecture of claim 13, further comprising a control unit that produces a signal, operably interconnecting said seat component and said unitary electronics distribution system wherein said signal from said control unit allows a user to manipulate the signal distributed by said unitary electronics distribution system.

5

10

15. The airline seat architecture of claim 13, further comprising an interconnection system that operably interconnects said unitary electronics distribution system and said seat component.

16. The airline seat architecture of claim 15, wherein said interconnection system is a ribbon cable.

17. The airline seat architecture of claim 16, wherein said
 15 interconnection system interconnects a plurality of said unitary electronics distribution systems in a plurality of individual airline seats.

18. A seat assembly for an aircraft comprising:

a seat portion including at least one of a seat back and a seat cushion adapted to be used by a passenger in an aircraft;

a support structure that suspends said seat portion above a surface;

a plurality of passenger usable electronic components, including a video display unit, a telephone, an audio output, and a personal computer port, extending from said seat portion;

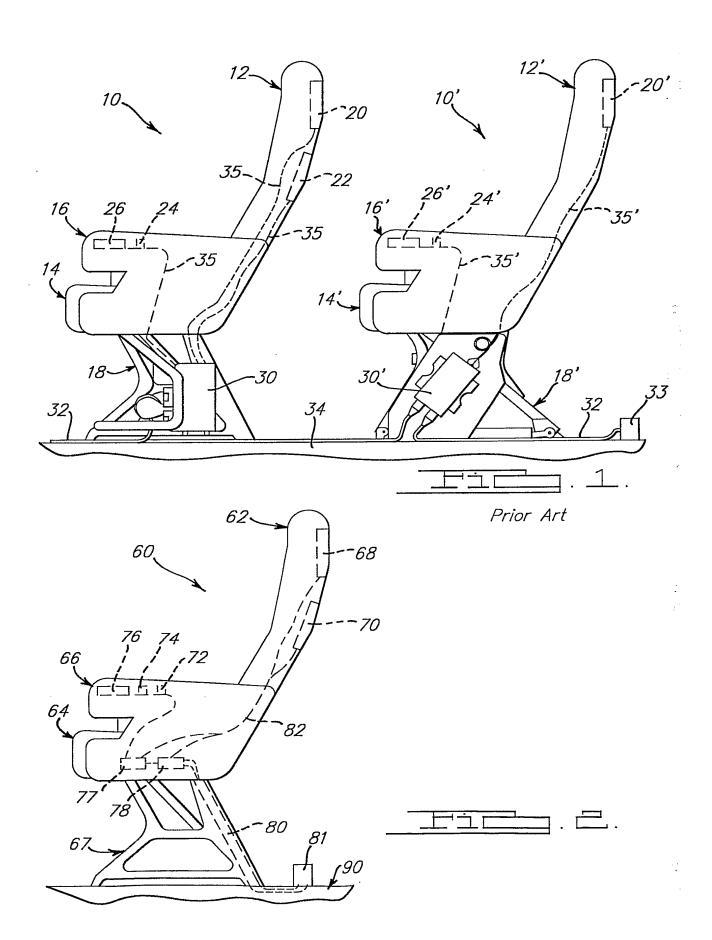

a single power converter to transmit power to each of said 10 plurality of electronic components; and

a ribbon cable operably associated with said power supply and including a plurality of conductors that transmit power through at least one of said plurality of conductors to said single power converter.

- 19. The seat assembly of claim 18, further comprising a single router to transmit the appropriate data signal to or from each of said plurality of electronic components; and
- wherein at least one other of said plurality of conductors carries a signal to or from said single router.

5

20. The seat assembly of claim 19, further comprising a plurality of the seat assemblies wherein said ribbon cable operably interconnects said plurality of electronic components extending from the plurality seat assemblies.
